

Make Error Handling the Users' Problem

(They will thank you for it)

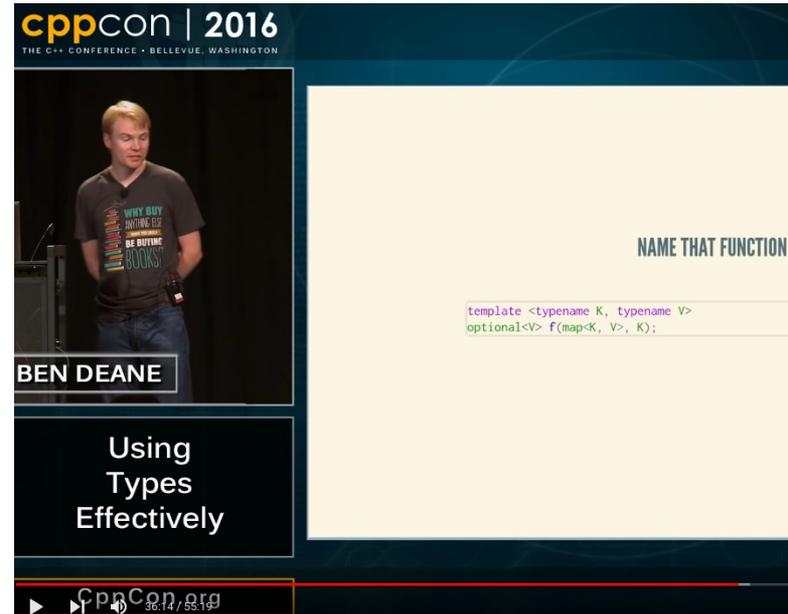

Søren Rune Nissen

soren.nissen+mcpp@gmail.com

Inspired by Ben Deane

(And a problem I had at work)

- Write total functions
- They're easier to understand
- They're easier *to write*

The image shows a video player interface for a presentation at CppCon 2016. The speaker is Ben Deane, wearing a t-shirt that says "WHY BUY ANYTHING ELSE BE BUYING THE BUCKS!". The slide title is "Using Types Effectively". The main content of the slide is "NAME THAT FUNCTION" followed by a C++ code snippet:

```
template <typename K, typename V>
optional<V> f(map<K, V>, K);
```

 The video player shows a progress bar at 36:14 / 55:19.

Example

```
auto count_vowels(char const *)
```

But what about - nullptr

Throw ?

std::pair<error, count> ?

UB ?

Example

```
size_t count_vowels(string_view)
```

Practically implements itself

No weird edge cases

Solid return type

No need to read documentation!

Example

```
size_t count_vowels(string_view)
```

```
auto reciprocal(double d)
{
    //precondition: d != 0
    //precondition: d != inf
    //precondition: d != nan

    return 1.0/d;
}
```

Example

```
size_t count_vowels(string_view)      auto reciprocal(Divisor d)
{                                       {
|                                       |   return 1.0/d;
}                                       }
```

Does your codebase use exceptions?

- Throw in the constructor

Do it not not?

- Private constructor
- Static function `std::optional<Divisor> factory(double d);`

Nobody wants to read
all the documentation
for a whole new class
for every input parameter

Consider using a framework

ConstrainedMath.h

```
using Divisor = Constrained < double, Not<0.0>, Finite >;  
double reciprocal(Divisor D);
```

ConstrainedMath.cpp

```
#include "ConstrainedMath.h"  
double reciprocal(Divisor d)  
{  
    return 1.0/d;  
}
```

In Conclusion

Enforce preconditions with invariants

Let your users select error handling using CTOR or factory method

Instead of writing and documenting a lot of parameter functions, consider using a framework to save time and to give the user a common type so they only have to read the documentation once.
